

Supplementary Figure 1. Changes in C statistics with the addition of albuminuria and eGFR levels (or traditional cardiovascular predictors) to conventional (or four-variable) models. Base C statistics were calculated in four-variable models. The primary composite outcome was major cardiovascular events or kidney disease progression. The secondary composite outcome was major cardiovascular events or kidney failure. Kidney disease progression was defined as serum creatinine doubling or kidney failure.

*The marked C statistics were calculated in conventional models.

ASCVD, atherosclerotic cardiovascular disease; CI, confidence interval; eGFR, estimated glomerular filtration rate.
